Recap: Ordering tables

To do more with tabular data, first include the textbook library: include shared-gdrive("dcic-2021", "1wyQZj_L0qqV9Ekgr9au6RX2iqt2Ga8Ep"

We can transform tabular data to get a particular view. E.g., to order the rows from the highest 2020 population to the lowest: >>> order-by(municipalities, "pop-2020", false)

name	kind	pop-2010	pop-2020
"New York"	"City"	8175133	8804190
"Hempstead"	"Town"	759757	793409
"Brookhaven"	"Town"	486040	485773
"Islip"	"Town"	335543	339938
"Oyster Bay"	"Town"	293214	301332
"Buffalo"	"City"	261310	278349
"North Hempstead"	"Town"	226322	237639

We can transform tabular data to get a particular view. E a to order the rolewest m the highest 2020 por highe st order-by(municipancies, "pop-2020", false)

name	kind

Recap: Filtering tables

We can use filter-with to get just the towns: fun is-town(r :: Row) -> Boolean: doc: "Check if a row is for a town" r["kind"] == "Town" end

filter-with(municipalities, is-town)

Or we could mke a table keeping only those municipalities with a population over 10,000: fun big-muni(r :: Row) -> Boolean: doc: "Return true if the municipality had over 10,000 people had in 2020" r["pop-2020"] > 10000 end

>>> filter-with(municipalities, big-muni)

name	kind	pop-2010	pop-2020
"Airmont"	"Village"	8628	10166
"Albany"	"City"	97856	99224
"Amherst"	"Town"	122366	129595
ll America ad a mili		10620	10210

PROBLEM Figure out what the fastest-growing towns are in New York.

Subtasks: Filtering to just towns Calculating percentage change in population Building a column for percentage change Sorting on that column in *descending* order

Subtasks: Filtering to just towns Calculating percentage change in population Building a column for percentage change Sorting on that column in *descending* order

towns = filter-with(municipalities, is-town)

Subtasks: Filtering to just towns Calculating percentage change in population Building a column for percentage change Sorting on that column in descending order

towns = filter-with(municipalities, is-town)

fun percent-change(r :: Row) -> Number: doc: "Compute the percentage change for the population of a municipality between 2010 and 2020" (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"] end

> We can write a function that takes a row as input and returns any kind of value, not just a Boolean.

Subtasks:

Filtering to just towns Calculating percentage change in population Building a column for percentage change Sorting on that column in *descending* order

towns = filter-with(municipalities, is-town)

fun percent-change(r :: Row) -> Number: doc: "Compute the percentage change for the population of a municipality between 2010 and 2020" (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"] end

towns-with-percent-change =

build-column(towns, "percent-change",

percent-change)

Name of the function to use

Subtasks:

Filtering to just towns

Calculating percentage change in population

Building a column for percentage change

Sorting on that column in *descending* order

towns = filter-with(municipalities, is-town)

fun **percent-change**(r :: Row) -> Number: doc: "Compute the percentage change for the population of a municipality between 2010 and 2020" (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"] end

towns-with-percent-change =

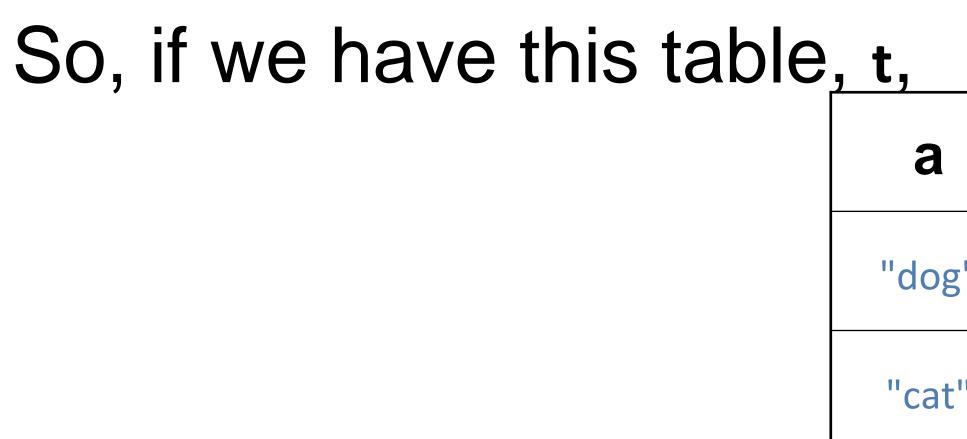

build-column(towns, "percent-change", percent-change)

fastest-growing-towns =

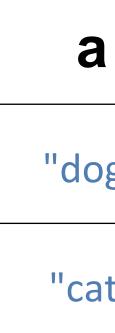

order-by(towns-with-percent-change, "percent-change", false)

fastest-growing-towns

Review: Building a column

then the result of calling build-column(t, "c", builder) is:

	b
g"	2
t"	3

	b	C
g"	2	builder(<"dog", 2>)
t"	3	builder(<"cat", 3>)

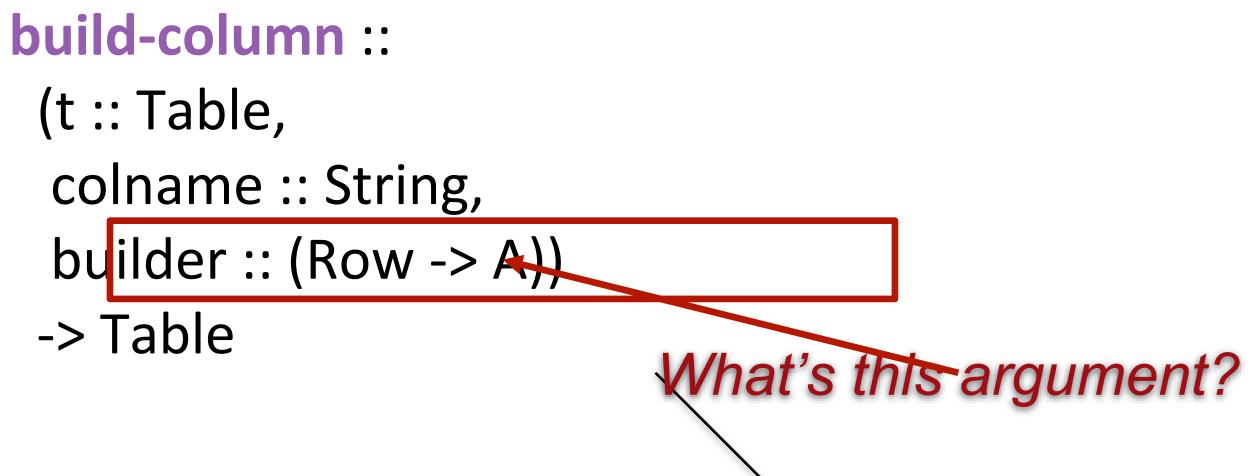

For example, if we have fun builder(r :: Row) -> Number: string-length(row["a"]) + row["b"] end

Then we end up with the following table:

b	С
2	5
3	6

The values that the builder function returns will be the values in the new column that we're adding to each row.

This is the second time we've seen a function that takes a function as one of its inputs!

Both filter-with and build-column need a helper function that tells them how to do what we want.

Just as a function is an abstraction over specific computations, filter-with and build-column are abstractions over more specific functions.

They provide the common functionality and the arguments we give provide the specifics.

Interlude: Functional programming

We can sort the rows a table with order-with, select certain rows using filter-with, and add a new column of values with build-column but none of these functions change the original table!

Just as the expression 2 + 3 doesn't change the value of 2 or of 3, functions that take a table as input don't change the original table. Instead, they return a *new* table.

This is a paradigm called *functional* programming.

If you have experience working in other languages, this may seem strange, but it can be extremely useful! We'll explore the idea of functional programming more in the coming weeks.

Loading Google Sheets into Pyret

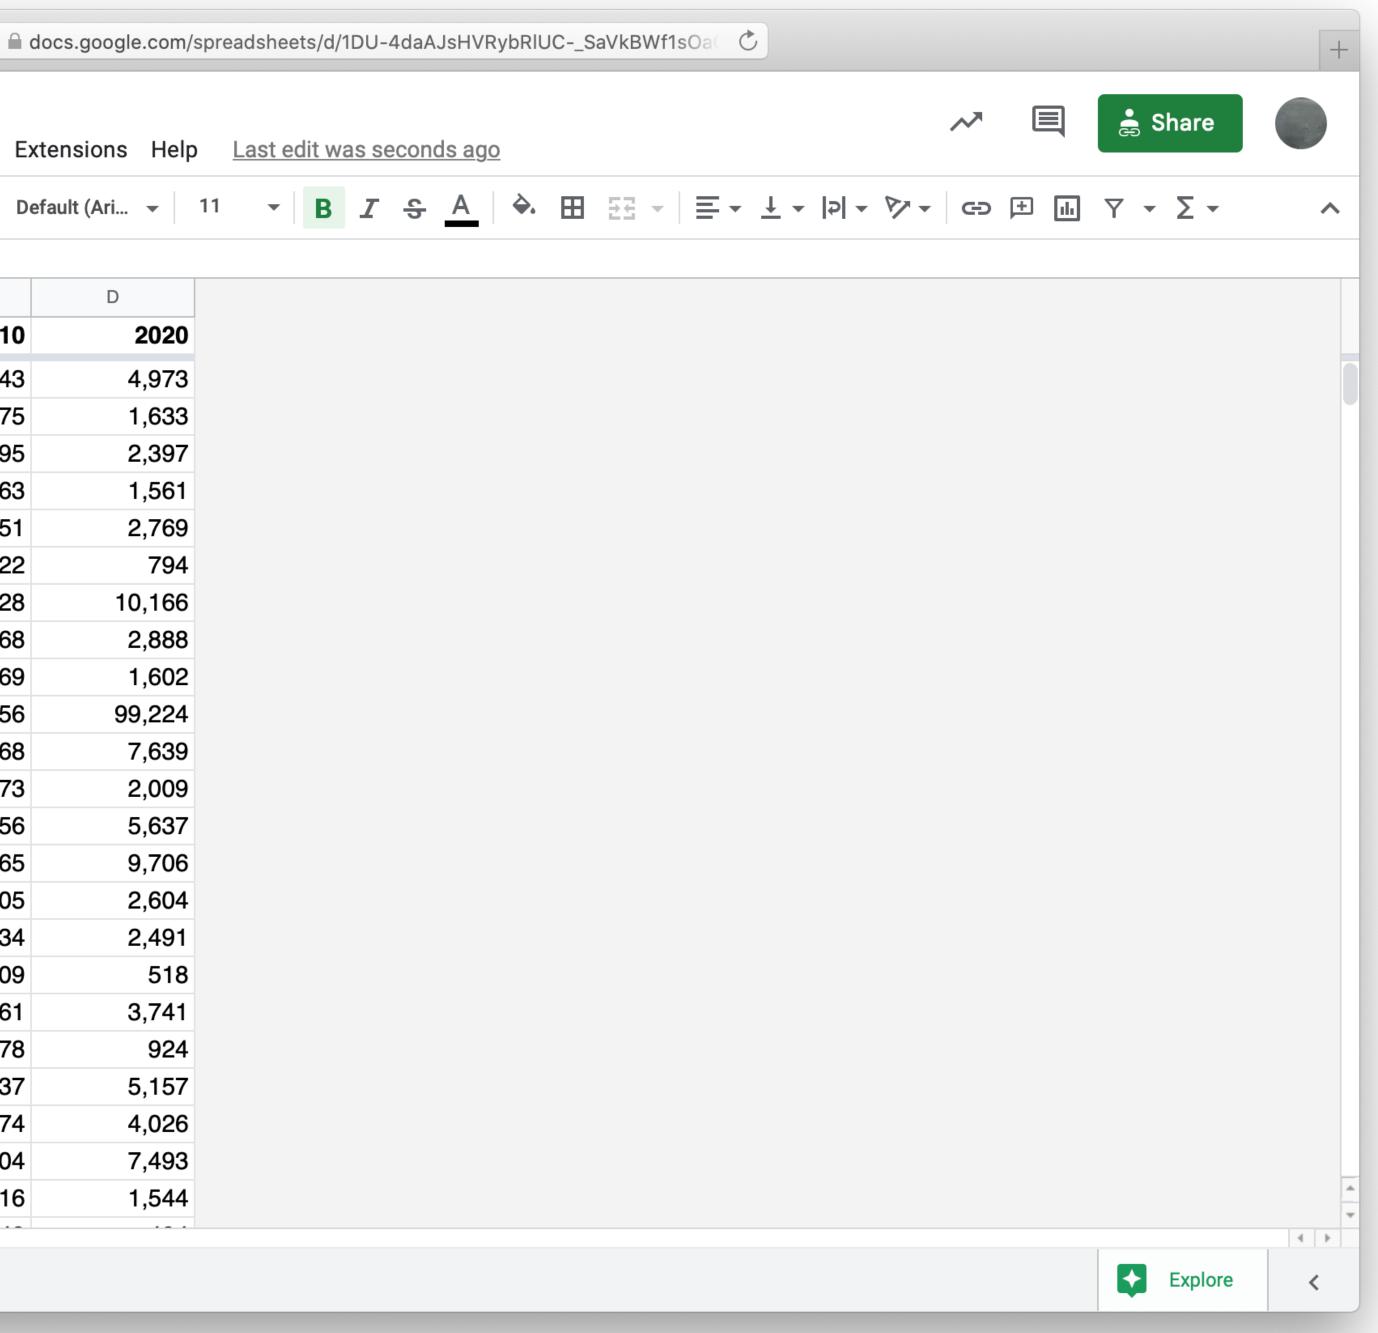

We've seen that it's inconvenient to type a large table into a Pyret program. Last time, we loaded the municipalities table from a separate Pyret file that I prepared ahead of time.

It's more usual to load a large data set from outside of Pyret.

+ ≡ municipalities ▼

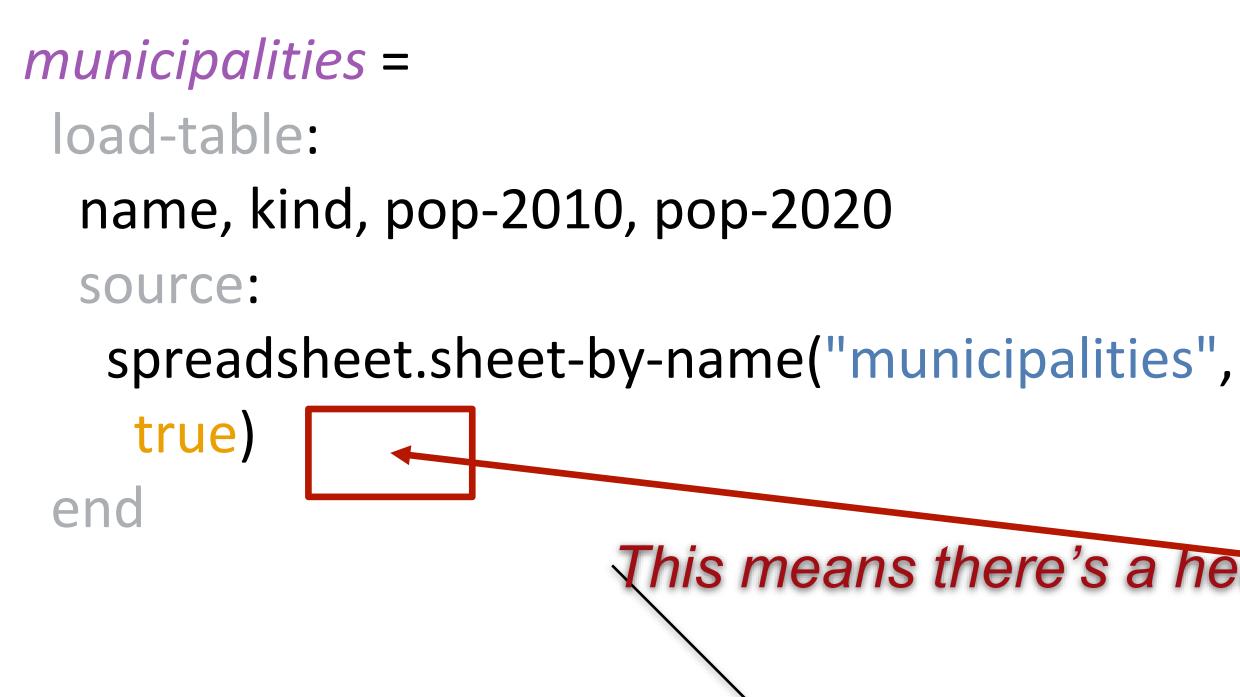

include gdrive-sheets

The ID of the Google Sheets file, which appears
in the URL
ssid = "1DU-4daAJsHVRybRIUC-_SaVkBWf1sOaGIfrWfgktIIs"

spreadsheet = load-spreadsheet(ssid)

A spreadsheet might have more than one sheet (the tabs at the bottom of Google Sheets). But, in this case, we just have one: >>> spreadsheet spreadsheet("municipalities")

To load a table from a spreadsheet, we need to tell Pyret which sheet to load it from and what we want the columns to be called (which can be different from what is in the spreadsheet):

This means there's a header row that Pyret should skip

Using our table loaded from Google Sheets, let's revisit our code from earlier for finding the fastest-growing towns.

```
fun is-town(r :: Row) -> Boolean:
 doc: "Check if a row is for a town"
 r["kind"] == "Town"
end
```

fun percent-change(r :: Row) -> Number: doc: "Compute the percentage change for the population of a municipality between 2010 and 2020" (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"] end

towns = filter-with(municipalities, is-town)

towns-with-percent-change = build-column(towns, "percent-change", percent-change)

fastest-growing-towns = order-by(towns-with-percent-change, "percent-change", false

fastest-growing-towns

Let's take these loose expressions and put them in a function!

```
fun is-town(r :: Row) -> Boolean:
 doc: "Check if a row is for a town"
 r["kind"] == "Town"
end
```

fun percent-change(r :: Row) -> Number: doc: "Compute the percentage change for the population of a municipality between 2010 and 2020" (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"] end

fun **fastest-growing-towns**(munis :: Table) -> Table: doc: "Return a table of towns ordered by their growth"

towns = filter-with(munis, is-town)

towns-with-percent-change =

build-column(towns, "percent-change", percent-change)

order-by(towns-with-percent-change, "percent-change", false) end

We've done a bit of a bad thing here: We've written three functions, but we don't have tests for any of them!

Let's see how we can rectify this.

Testing table functions

We can test table program by using test tables. These are tables that have the same structure as the table for our real data, but which are smaller and contain data that are useful for testing.

table: name, kind, pop-2010, pop-2020 row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

table: name, kind, pop-2010, pop-2020 row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

Let's see how we use these test data to write examples for our table functions.

table: name, kind, pop-2010, pop-2020 row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

```
fun is-town(r :: Row) -> Boolean:
  doc: "Check if a row is for a town"
  r["kind"] == "Town"
end
```

table: name, kind, pop-2010, pop-2020 row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

```
fun is-town(r :: Row) -> Boolean:
  doc: "Check if a row is for a town"
  r["kind"] == "Town"
  where:
    is-town(test-munis.row-n(0)) is false
    is-town(test-munis.row-n(1)) is true
    is-town(test-munis.row-n(3)) is false
  end
```

kind, pop-2010, pop-2020 table: name, row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

fun percent-change(r :: Row) -> Number:

doc: "Compute the percentage change for the population of a municipality between 2010 and 2020" (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"] end

table: name, kind, pop-2010, pop-2020 row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

fun percent-change(r :: Row) -> Number:

doc: "Compute the percentage change for the population of a municipality between 2010 and 2020"
 (r["pop-2020"] - r["pop-2010"]) / r["pop-2010"]
 where:

percent-change(test-munis.row-n(0)) is 0.01
percent-change(test-munis.row-n(1)) is 0.02
percent-change(test-munis.row-n(2)) is -0.01
end

table: name, kind, pop-2010, pop-2020 row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

fun fastest-growing-towns(munis :: Table) -> Table: doc: "Return a table of towns ordered by their growth" towns = filter-with(munis, is-town) towns-with-percent-change = build-column(towns, "percent-change", percent-change) order-by(towns-with-percent-change, "percent-change", false) end

kind, pop-2010, pop-2020 table: name, row: "Osgiliath", "City", 100, 101 row: "Lake-town", "Town", 100, 102 row: "Bree", "Town", 100, 99 row: "Hobbiton", "Village", 50, 54 end

fun **fastest-growing-towns**(munis :: Table) -> Table: . . . where: *test-munis-after* = table: name, kind, pop-2010, pop-2020, percent-change

```
row: "Lake-town", "Town", 100, 102, 0.02
```

row: "Bree", "Town", 100, 99, -0.01

end

fastest-growing-towns(test-munis) is test-munis-after end

Don't just copy the function's output; think through what it's supposed to do!

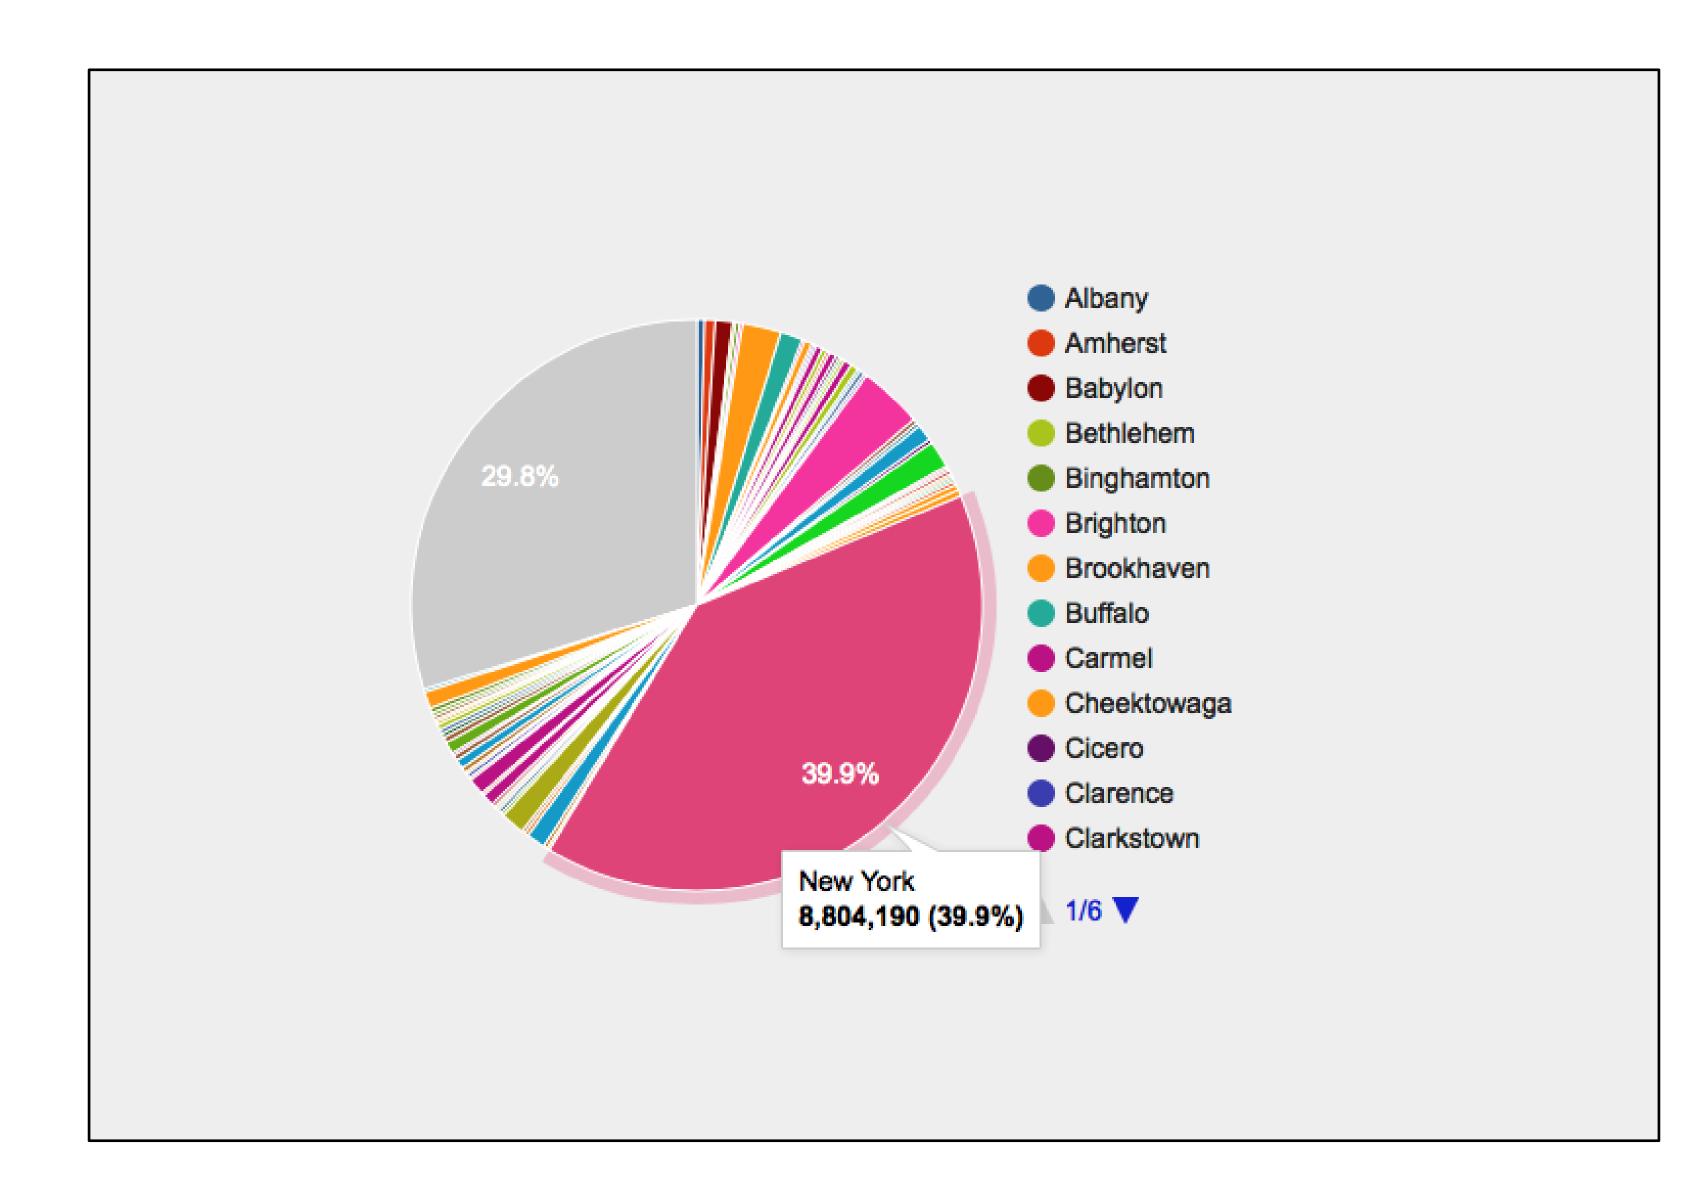

Visualization

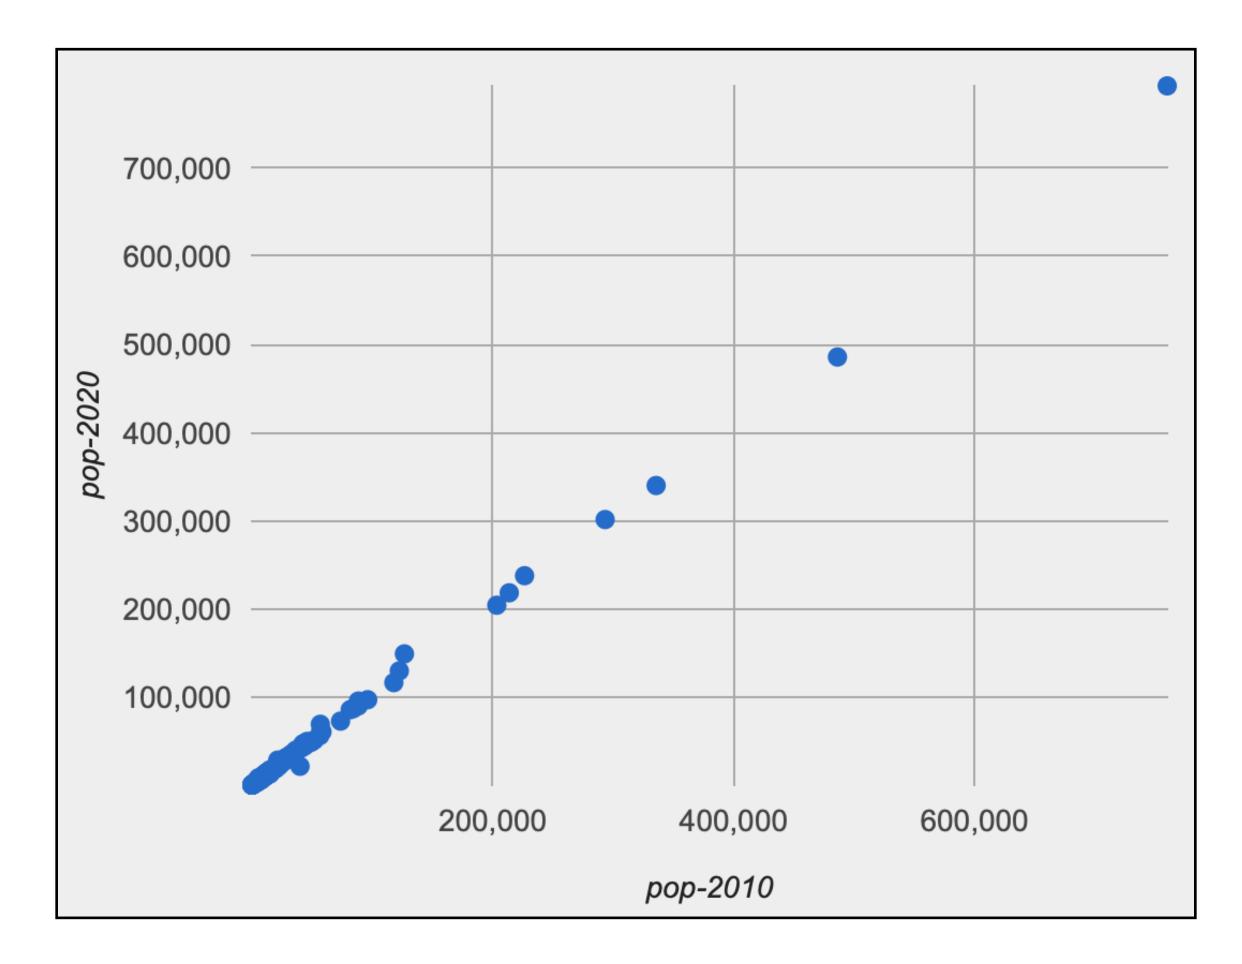

Data scientists use plots for both *exploratory* and explanatory purposes – they are useful for understanding data in preparation for further analysis and in presenting data to a general audience.

The dcic-2021 library we've been using to work with tables includes several functions to generate different kinds of plots like the ones we've talked about.

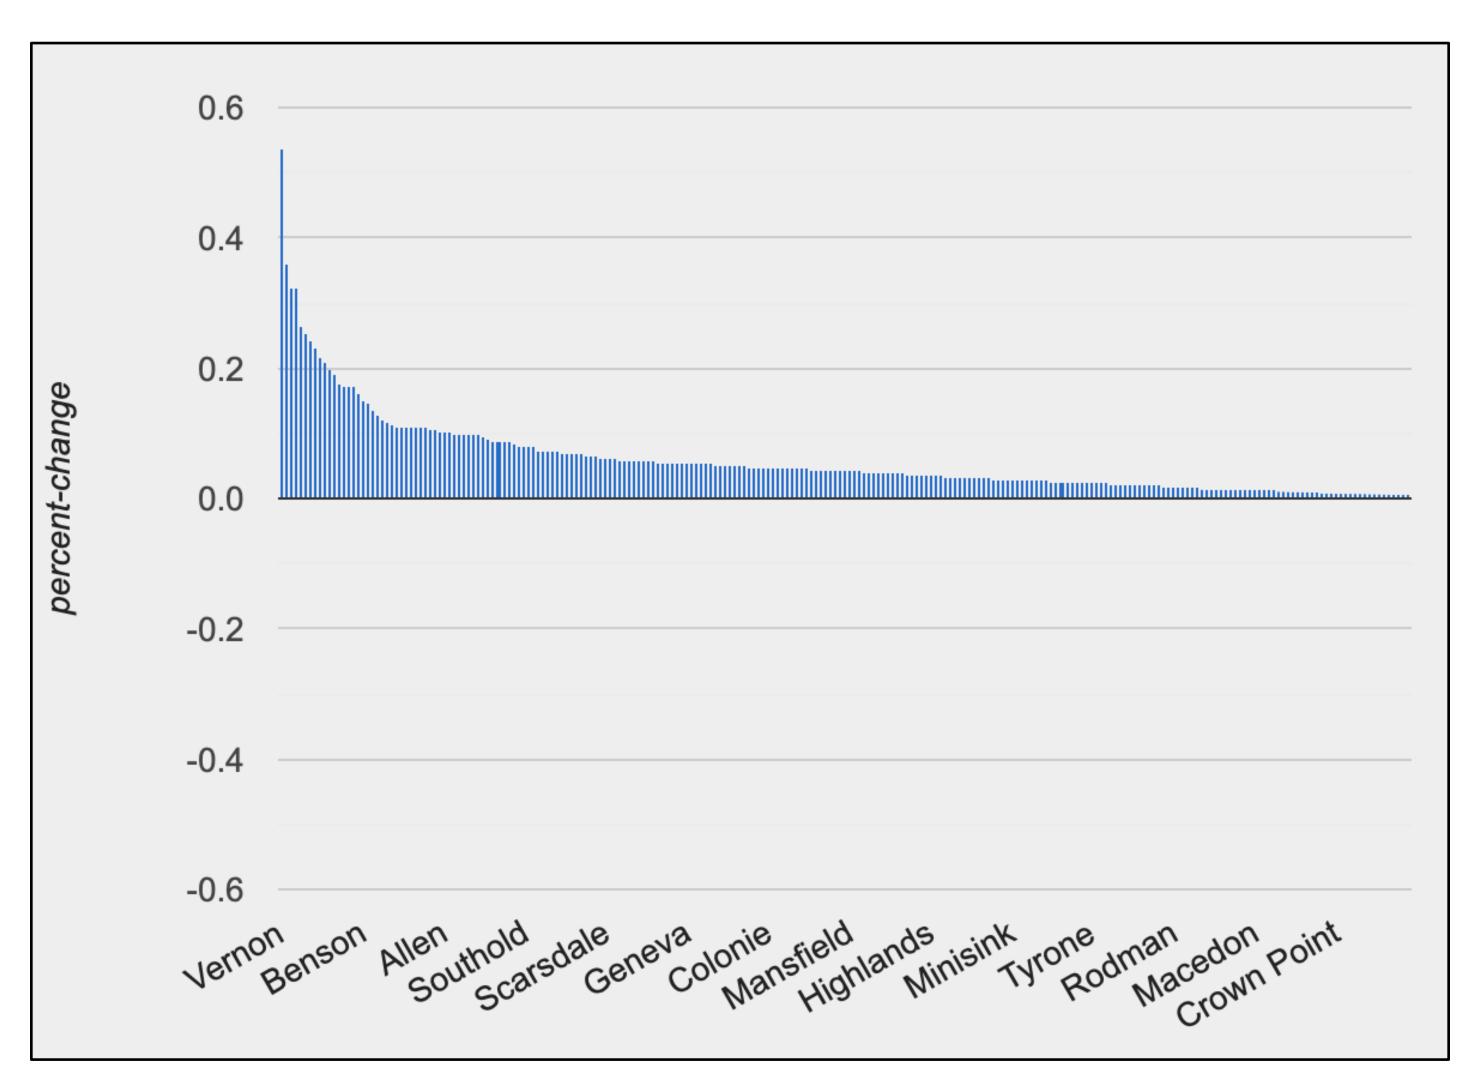

How is population distributed in the state? pie-chart(municipalities, "name", "pop-2020")

Is a town's population in 2010 correlated with *# its population in 2020?* scatter-plot(ft, "pop-2010", "pop-2020")

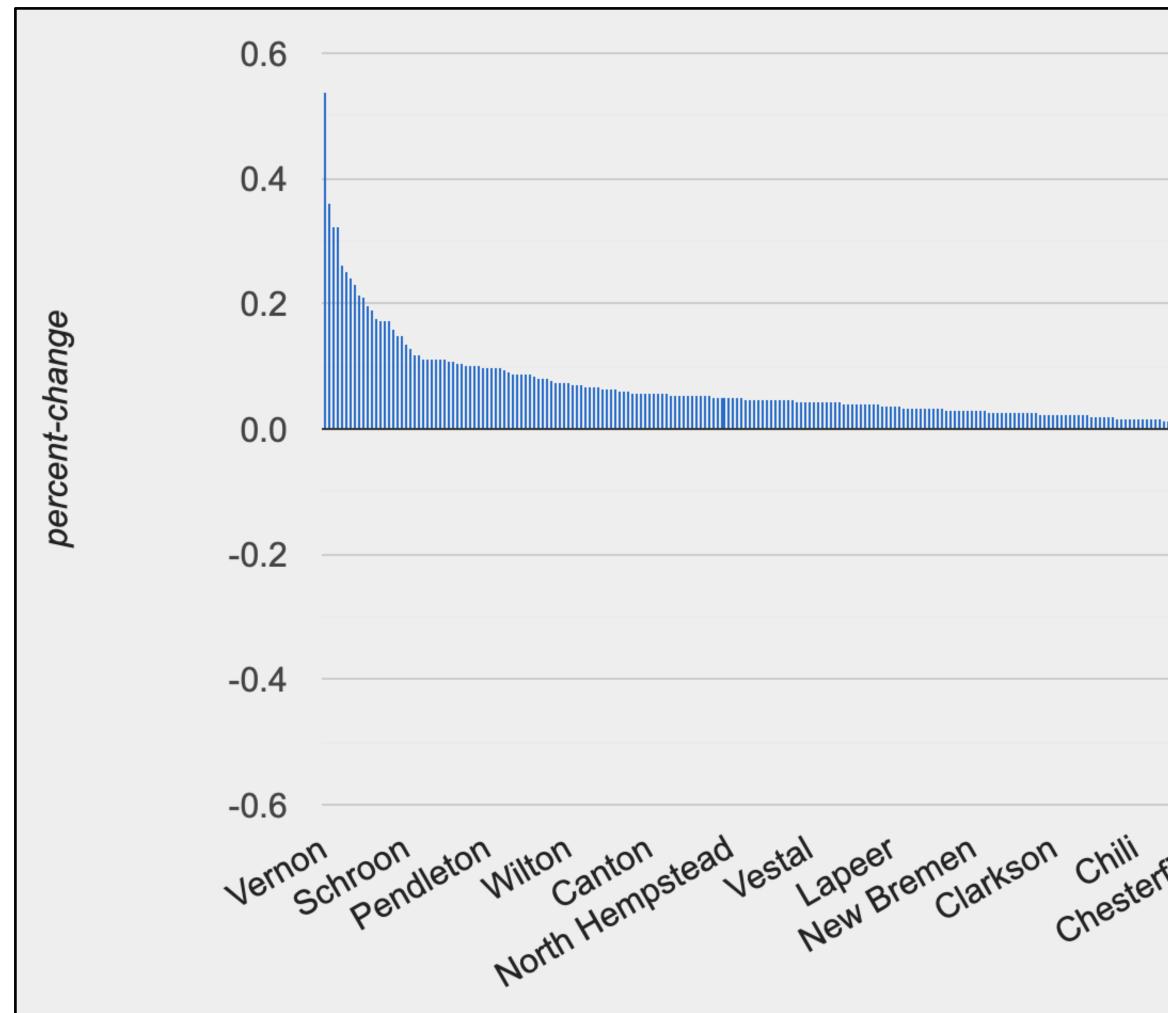

Visually present the growth data bar-chart(ft, "name", "percent-change")

...didn't any towns shrink?
