Lecture Notes

CS377 - Parallel Programming

Marc L. Smith

Linda and Tuple Space

(Ruby and Rinda)

The Linda Model

- A communication and coordination model for concurrent processes
- Augments any existing sequential programming language
- Consists of
  - Tuple Space -- a global shared memory
  - 4 primitive operations on Tuple Space

The Linda Model

- Tuple Space -- a container of tuples
- tuple -- an ordered sequence of typed values, or value-yielding computations
    - a tuple whose values are all computed is passive
    - a tuple with at least one value still being computed is active

The Linda Model

- The Linda primitive operations:
  - rd( ) -- “read” -- to match tuples in TS
  - in( ) -- to match/remove tuples from TS
  - out( ) -- to place new tuples in TS
  - eval( ) -- to create new Linda processes
    (places active tuple in TS)
- first two ops are synchronous (blocking) *
  * non-blocking versions also exist: rdp( ) and inp( )
- last two operations are asynchronous (non-blocking)
- first three operations operate on passive tuples.

The Linda Model

- Tuple Space
  - a distributed shared memory
  - not addressable memory
    (no pointers to tuples!)
  - an associative memory
    (tuples are matched)

The Linda Model

- Tuple matching is a generalization of how we use hashmaps
- Hashmaps
  - key - value pairs
  - lookup key; return corresponding value
- Tuples
  - multiple keys possible (by position within tuple)
  - multiple corresponding values possible (by position)

Rinda

- An implementation of the Linda Model
  - Base language: Ruby
  - augmented with read(), take(), and write()
    - eval() not implemented
    - predicate operations rdp() and inp() implemented as optional parameters of read() and take()—we won't be using
- Let's look at some examples!

Producer/Consumer

- Two processes: Producer and Consumer
- Each process has its own array of n elements.
- Between the two processes, a shared buffer exists that will be used to transfer the contents of the producer's buffer to the consumer's buffer, one element at a time

Producer/Consumer using shared variables

- Here's the pseudo code for producer and consumer:

```
//shared variables
int buf, n = 80,  p = 0,  c = 0;
```

```
process Producer {
  int a[n];
  while (p < n) {
    << await (p == c); >>
    buf = a[p];
    p = p+1;
  }
}
```

```
process Consumer {
  int b[n];
  while (c < n) {
    << await (p > c); >>
    b[c] = buf;
    c = c+1;
  }
}
```

Semaphores in Rinda

- P(s): ts.take([“sem”])
  - attempts to match/remove a one-field tuple in TS
- V(s): ts.write([“sem”])
  - places a one-field tuple in TS
- For multiple semaphores
  - you decide how to implement...

Producers/Consumers using semaphores

- Here's the pseudo code for producer and consumer procs:

```
//shared variables
int buf;
sem empty = 1;
sem full = 0;
```

//binary semaphores: 0 or 1

```
process Producer(i) {
  while (true) {
    . . .
    // produce data,
    // deposit in buf.
    P(empty);
    buf = data;
    V(full);
  }
}
```

```
process Consumer(i) {
  while (true) {
    //fetch data from buf,
    //and consume it.
    P(full);
    result = buf;
    V(empty);
    . . .
  }
}
```

Bounded Buffer using semaphores

- Here's the pseudo code for producer and consumer procs:

```
//shared variables
int buf[n],
int front = 0, rear = 0;
sem empty = n, full = 0;
```

//counting semaphores
//range from 0 to n

```
process Producer {
  while (true) {
    . . .
    // produce data,
    // deposit in buf.
    P(empty);
    buf[rear] = data;
    rear = (rear+1)%n;
    V(full);
  }
}
```

```
process Consumer {
  while (true) {
    //fetch data from buf,
    //and consume it.
    P(full);
    result = buf[front];
    front = (front+1)%n;
    V(empty);
    . . .
  }
}
```

Programming Assignment 6 Due: Fri, Dec. 4, 2020

- Implement Ruby/Rinda versions of the producer/consumer and bounded buffer problems (slides 11 and 12) using semaphores.
- Augment with print statements indicating who is producing / consuming what and when.

Question

- How would you handle a bounded buffer with multiple producers and consumers?

Semaphores (review)

- Binary
  - values = 0 / 1
  - operations: P(s) and V(s)
- Split Binary
  - split one semaphore into two
  - $0 <= s1 + s2 <= 1$

Semaphores (review)

- Counting
  - values = 0, 1, 2, ...
  - operations: still P(s) and V(s)
  - useful for managing fixed no. of resources
- Linda implementation
  - very natural mapping to in() and out()
  - very natural extension from binary to counting

Producer / Consumer

- All versions use split binary semaphores (e.g., empty, full)
- Version 1:
  - multiple producers / consumers
  - single shared buffer
- Version 2:
  - single producer / single consumer
  - bounded buffer (an array)

Producer / Consumer

- Question: how would you handle a bounded buffer with multiple producers and consumers?
- We solved each problem separately already!
  - Version 1: multiple producers / consumers with single buffer
  - Version 2: single producer / consumer with bounded buffer (n elements)

Producer / Consumer (combined solution)

- Here's the pseudo code for producer and consumer procs:

```
//shared variables
int buf[n],
int front = 0, rear = 0;    // indices to buf
sem empty = n, full = 0;    // between producers/consumers
sem mutexD = 1,             // between different producers
    mutexF = 1;             // between different consumers
```

```
process Producer[i = 1 to M] {
  while (true) {
    . . .
    // produce data; deposit in buf
    P(empty);
      P(mutexD);
        buf[rear] = data;
        rear = (rear+1)%n;
      V(mutexD);
    V(full);
  }
}
```

```
process Consumer[j = 1 to N] {
  while (true) {
    //fetch data from buf; consume it.
    P(full);
      P(mutexF);
        result = buf[front];
        front = (front+1)%n;
      V(mutexF);
    V(empty);
    . . .
  }
}
```

Semaphores (Rinda implementation)

```
// Semaphore primitives P and V (works for binary and counting sems)
// -- must be implemented over tuples in tuple space
```

So this invocation:

```
P(empty)
```

is implemented like this in Ruby/Rinda:

```
tag, n = ts.take( [“empty”] )
```

and this invocation:

```
V(full)
```

is implemented like this in Ruby/Rinda:

```
ts.write( [“full”] )
```

Semaphore usage (binary / counting)

binary initialization:

```
sem full = 0;
sem empty = 1;
```

Becomes this in your C-Linda code:

```
V("empty");

// places a tuple in TS:
// ("sem", "empty")

// do nothing to initialize
// semaphore full = 0...
```

counting initialization:

```
sem empty = n;
sem full = 0;
```

Becomes this in your C-Linda code:

```
for (i=0, i<n; i++) {
  V("empty");
}

// places n tuples in TS
// that all look like this:
// ("sem", "empty")
```

Bounded buffer in Tuple Space

```
// C declaration of a buffer as an array of ints
int buf[n];

// Assignment of three elements to buf
buf[0] = 42;
buf[1] = 43;
buf[2] = 44;

// Equivalent assignment using distributed data
// structure in tuple space...
// Tuples of this form are used:
//
//   ("buf", index, value)

ts.write("buf", 0, 42);
ts.write("buf", 1, 43);
ts.write("buf", 2, 44);

// to access value stored in buf[13]...
int i, value;
i = 13;
tag, index, val = ts.read("buf", 13, Numeric);

//to consume same data, change rd() to in()...
tag, index, val = ts.take("buf", 13, Numeric);
```

Producer / Consumer Version 3

- Here's the pseudo code for producer and consumer procs:

```
//shared variables -- must be implemented in tuple space
int buf[n],
int front = 0, rear = 0;    // indices to buf
sem empty = n, full = 0;    // between producers/consumers
sem mutexD = 1,             // between different producers
    mutexF = 1;             // between different consumers
```

```
process Producer[i = 1 to M] {
  while (true) {
    . . .
    // produce data; deposit in buf
    P(empty);
      P(mutexD);
        buf[rear] = data;
        rear = (rear+1)%n;
      V(mutexD);
    V(full);
  }
}
```

```
process Consumer[j = 1 to N] {
  while (true) {
    //fetch data from buf; consume it.
    P(full);
      P(mutexF);
        result = buf[front];
        front = (front+1)%n;
      V(mutexF);
    V(empty);
    . . .
  }
}
```

Producer / Consumer Version 3

- Here’s how to initialize tuple space with this shared data:

```
//shared variables -- must be implemented in tuple space
int buf[n],
int front = 0, rear = 0;    // indices to buf
sem empty = n, full = 0;    // between producers/consumers
sem mutexD = 1,             // between different producers
    mutexF = 1;             // between different consumers
```

```
// nothing for buf[n]  -- until data produced...

out(“front”, 0);    out(“rear”, 0);

for (i = 0, i < n, i++) {
  V(“empty”);
}
// nothing for full -- until producer produces something

V(“mutexD”);
V(“mutexF”);
```
