Table.where Predicates

All of the predicates described below can be negated by preceding the name with `not_`. For example, we can find values *not* equal to a specific value using `are.not_equal_to(value)`.

`are.equal_to()`

```
tbl.where(column, are.equal_to(value))
```

Filter leaves rows only where the value in `column` is equal to `value`.

```
[166]: trips.where("Duration", are.equal_to(519))
```

[166]:

What about columns?

stats =

Player	Team	Pos	Games	Pts
Monique Akoa Makani	PHO	G	41	315

Lindsay Allen	CON	G	31	74
Rebecca Allen	CHI	F-G	44	225

Yvonne Anderson	MIN	G	1	0
Ariel Atkins	CHI	G	34	447
Shakira Austin	WAS	F-C	38	481
Marième Badiane	MIN	C	3	0

```
stats["Pts"]
```

How do I get just the points column?

```
stats["Pts"]
```

→

```
array([228, 133, 17, 532, ...])
```

```
stats["Pts"]
```

→ `array([228, 133, 17, 532, ...])`

The data type isn't Column; it's an array!

Notebook:

Exercise: Who scores the most points per game?

So, we've seen that we can build a new column based on the values in each row, but what if we just want to change an existing column?

A fake WNBA fan like me can't remember what these team abbreviations stand for.

Let's fill in the actual team names.

What *are* the team names?
